Computer Graphics Seminar

MTAT.03.305

Fall 2014
Computer Graphics

- Graphical illusion via the computer
- Displaying something meaningful (inc art)
Math

• Computers are good at... computing.
• To do computer graphics, we need math for the computer to compute.
• Geometry, algebra, calculus.

\[
\begin{bmatrix}
a & b & c & d \\
e & f & g & h \\
i & j & k & l \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\begin{bmatrix}
x \\
y \\
z \\
1 \\
\end{bmatrix}
= 
\begin{bmatrix}
ax + by + cz + d \\
ex + fy + gz + h \\
ix + jy + kz + l \\
1 \\
\end{bmatrix}
\]
Point

- Simplest geometry primitive
- In homogeneous coordinates: $(x, y, z, w), w \neq 0$

- Represents a point $(x/w, y/w, z/w)$
- Usually you can put $w = 1$
- Actual division will be done by GPU later
Line (segment)

- Consists of:
  - 2 endpoints
  - *Infinite* number of points between
- Defined by the endpoints
- Interpolated in GPU

\[(x_1, y_1, z_1, 1)\]
\[(x_2, y_2, z_2, 1)\]
Triangle

- Consists of:
  - 3 points called vertices
  - 3 lines called edges
  - 1 face

- Defined by 3 vertices

- Lines and face will be interpolated in GPU

- Counter-clockwise order defines front face
Why triangles?

- They are in many ways the simplest polygons
  - 3 different points always form a plane
  - Easy to rasterize (fill the face with points)
  - Every other polygon can be converted to triangles
- OpenGL used to support other polygons too
  - Must have been:
    - Simple – No edges intersect each other
    - Convex – All points between any two points are inner points
Examples of polygons
OpenGL < 3.1 primitives

Figure 3.2  Vertex layout for a triangle fan

In the beginning there were points

- Now that we can define our geometric objects, what next?
- We want to move our objects!

Luckily GPU will do this work for us.
Transformations

- It turns out that homogeneous coordinates allows us to easily do:
  - Linear transformations
    - Scaling, reflection
    - Rotation
    - Shearing
  - Affine transformations
    - Translation (shifting)
  - Projection transformations
    - Perspective
    - Orthographic

Actually these we could do without homogeneous coordinates...

This too...
Transformations

- Every transformation is a function
- As you remember from Algebra, linear functions can be represented as matrices

\[ f(v) = (2x, y, z) = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} x \\ y \\ z \end{pmatrix} \]

\[ v \in \mathbb{R}^3 \]

\[ v = (x, y, z) \]

You should transpose the result later.
Transformations

- GPU-s are built for doing transformations with matrices.
- Remember, computers are made for computing.
- Let's look at some linear transformations...

\[ f(a_1 x_1 + \ldots + a_n x_n) = a_1 f(x_1) + \ldots + a_n f(x_n) \]

We don't use homogeneous coordinates at the moment, don't worry, they'll be back...
Scaling

- Redefines the basis vectors as some multiple of the previous basis vectors.

\[
\begin{pmatrix}
2 & 0 \\
0 & 1 \\
\end{pmatrix} \cdot \begin{pmatrix}
x \\
y \\
\end{pmatrix} = \begin{pmatrix}
\times \\
\times \\
\end{pmatrix}
\]

\[
\begin{pmatrix}
2 & 0 \\
0 & 1 \\
\end{pmatrix} \cdot \begin{pmatrix}
1.5 \\
1.5 \\
\end{pmatrix} = \begin{pmatrix}
3 \\
1.5 \\
\end{pmatrix}
\]
Scaling

- In general we could scale each axis

\[
\begin{pmatrix}
  a_x & 0 & 0 \\
  0 & a_y & 0 \\
  0 & 0 & a_z \\
\end{pmatrix}
\]

- \(a_x\) – x-axis scale factor
- \(a_y\) – y-axis scale factor
- \(a_z\) – z-axis scale factor

- If some factor is negative, this matrix will reflect the points from that axis. Thus we get reflection.
Shearing

- Not much used by itself, but remember it for translations later.
- Rotates only one axis.
- Squares become parallelograms.

\[
\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \cdot \begin{pmatrix} 0 \\ 2 \end{pmatrix} = \begin{pmatrix} 0 \\ 2 \end{pmatrix}
\]

\[
\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 \\ 2 \end{pmatrix} = \begin{pmatrix} 1 \\ 3 \end{pmatrix}
\]
Shearing

- Shear-x, we tilt x basis vector by angle $\phi$ counter-clockwise

\[
\begin{pmatrix}
1 & 0 \\
\tan(\phi) & 1 \\
\end{pmatrix}
\begin{pmatrix}
x \\
y \\
\end{pmatrix}
= 
\begin{pmatrix}
x \\
y + \tan(\phi) \cdot x \\
\end{pmatrix}
\]

- Shear-y, we tilt y basis vector by angle $\phi$ clockwise

\[
\begin{pmatrix}
1 & \tan(\phi) \\
0 & 1 \\
\end{pmatrix}
\begin{pmatrix}
x \\
y \\
\end{pmatrix}
= 
\begin{pmatrix}
x + \tan(\phi) \cdot y \\
y \\
\end{pmatrix}
\]
Rotation

- Shearing rotated only one axis
- Also changed the size of the basis vector
- Can we do better?

Did you notice that the columns of the transformation matrix show the coordinates of the new basis vectors?
Rotation

\[ e'_0 = (|a|, |b|) = (\cos(\alpha), \sin(\alpha)) \]
\[ e'_1 = (|a'|, |b'|) = (-\sin(\alpha), \cos(\alpha)) \]

\[ \cos(\alpha) = \frac{|a|}{|e'_0|} = \frac{|a|}{1} = |a| \]
Rotation

- So if we rotate by $\alpha$ in counter-clockwise order in 2D, the transformation matrix is:

$$
\begin{pmatrix}
\cos(\alpha) & -\sin(\alpha) \\
\sin(\alpha) & \cos(\alpha)
\end{pmatrix}
$$

- In 3D we can do rotations in each plane (xy, xz, yz), so there can be 3 different matrices.
Rotation

- To do a rotation around an arbitrary axis, we can:
  - Rotate that axis to be the x-axis
  - Rotate around the new x-axis
  - Invert the first rotations (move the old x-axis back)

- OpenGL provides a command for rotating around a given axis.

- Sometimes quaternions are used for rotations.

Quaternions are elements of a number system that extend the complex numbers...
Do we have everything now?

- We can scale, share and rotate our geometry around the origin...

What if we have an object not centered in the origin?
Translation

- Imagine that our 1D world is located at $y=1$ line in 2D space.

- Notice that all the points are in the form: $(x, 1)$
Translation

- What happens if we do shear-\(y(45^\circ)\) operation on the 2D world?

- Everything in our world has moved magically one x-coordinate to the right...

\[\tan(45^\circ) = 1\]
Translation

- What if we do shear-y(63.4°)?
- Everything has now moved 2 x-coordinates to the right from the original position
- We can do translation / shift!

\[
\tan(63.4°) = 2
\]
Translation

• When we represent our points in one dimension higher space, where the extra coordinate is 1, we get to the **homogeneous** space.

\[
\begin{pmatrix}
1 & x_t \\
0 & 1
\end{pmatrix} \cdot \begin{pmatrix}
x \\
1
\end{pmatrix} = \begin{pmatrix}
x + x_t \\
1
\end{pmatrix}
\]

\[
\begin{pmatrix}
1 & 0 & x_t \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix} \cdot \begin{pmatrix}
x \\
y \\
z
\end{pmatrix} = \begin{pmatrix}
x + x_t \\
y + y_t \\
z + z_t
\end{pmatrix}
\]
Transformations

- This together gives us a very good toolset to transform our geometry as we wish.

\[
\begin{pmatrix}
  a & b & c & x_t \\
  d & e & f & y_t \\
  g & h & i & z_t \\
  0 & 0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
  x \\
  y \\
  z \\
  1
\end{pmatrix} =
\begin{pmatrix}
  ax + by + cz + x_t \\
  dx + ey + fz + y_t \\
  gx + hy + iz + z_t \\
  1
\end{pmatrix}
\]

Used for perspective projection...
Multiple transformations

- Everything starts from the origin!
- To apply multiple transformations, just multiply matrices.
Multiple transformations

Our initial geometry defined by vertices: (-1, -1), (1, -1), (1, 1), (-1, 1)
Multiple transformations

\[
\begin{pmatrix}
\cos(45^\circ) & -\sin(45^\circ) & 0 \\
\sin(45^\circ) & \cos(45^\circ) & 0 \\
0 & 0 & 1
\end{pmatrix}
\]
Multiple transformations

\[
\begin{pmatrix}
1 & 0 & 4 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix}
\]
Multiple transformations

- We can combine the transformations to a single matrix.

\[
\begin{bmatrix}
1 & 0 & 4 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
\cos(45^\circ) & -\sin(45^\circ) & 0 \\
\sin(45^\circ) & \cos(45^\circ) & 0 \\
0 & 0 & 1
\end{bmatrix}
= \begin{bmatrix}
\cos(45^\circ) & -\sin(45^\circ) & 4 \\
\sin(45^\circ) & \cos(45^\circ) & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

- This also works for combining different linear transformations, but the resulting matrix isn't that clear...

- Order of transformations / matrices is important!

- [http://cgdemos.tume-maailm.pri.ee](http://cgdemos.tume-maailm.pri.ee)
Now we know how it's supposed to go...
OpenGL

• GPU API / middleware
• I.e a set of commands that program can give to GPU
• Supported in many languages
WebGL

- GPU API in JavaScript
- Supported by major browsers
- THREE.js – Higher level library to ease your coding: [http://threejs.org/docs/](http://threejs.org/docs/)
Forward is backward

- Actually you need to tell GPU commands in this order:
  - Transformations
  - Vertices

```c
glTranslatef(0.0, 0.0, -1.0);
glRotatef(60, 1.0, 0.0, 0.0);
glRotatef(-20, 0.0, 0.0, 1.0);

glBegin(GL_QUADS);
  glVertex3fv(...);
  glVertex3fv(...);
  glVertex3fv(...);
  glVertex3fv(...);
  glEnd();
```

Prior to OpenGL 3
State machine

- GPU acts like a state machine

```c
glBegin(GL_QUADS);
glVertex3fv(...);
glVertex3fv(...);
glVertex3fv(...);
glVertex3fv(...);
glEnd();
```

Prior to OpenGL 3
Multiple objects in the scene?

- Each object has its own geometry
- And its own transformations for that geometry
- OpenGL has a single ModelView matrix

```c
glTranslatef(0.0, 0.0, -1.0);
glRotatef(60, 1.0, 0.0, 0.0);
glRotatef(-20, 0.0, 0.0, 1.0);

glBegin(GL_QUADS);
  glVertex3fv(...);
  glVertex3fv(...);
  glVertex3fv(...);
  glVertex3fv(...);

  glEnd();
```

Prior to OpenGL 3
Multiple objects in the scene

- OpenGL has a matrix stack
- We can push a copy to the stack (save)
- We can pop the top matrix from the stack (load)

Prior to OpenGL 3
Multiple objects in the scene

- More complex geometry for a single object

Prior to OpenGL 3
Old and new OpenGL?

- Lot has changed from OpenGL 3.
- Everything old still works in compatibility mode.
